GuiGenie is a new and free Gui Builder designed for Java (and written in Java). GuiGenie features an intuitive interface that allows you to quickly and easily build GUIs using the Java swing package. The following is an overview of the functions, features and components available in GuiGenie.

You can also find additional information by clicking on: [\[?\] META-INF/README.txt](#) for the full details and how to use GuiGenie [\[?\]](#) [src/doc/README.txt](#) for a short user guide [\[?\] src/doc/examples/README.txt](#) for an extensive example application (that works fine with JDK 1.5.0 or newer) GuiGenie Features: 1) Drag and

Drop: You drag components from the left window into the right window. Each component represents a button, checkbox, combo box, text field, label, panel, or window. 2) Menu: You can make a list of items with different items 3) Keyboard: You can use the Keyboard to click on items. Items that cannot be clicked by keyboard

are grayed out. 4)

Components: By default, all standard java components are included.

You can also add new components such as JCheckBoxMenuItem, or JPanelMenuItem.

Components can be removed easily from the left side of the window.

Components such as JSpinner are available too.

5) JList: A JList is a list

that allows you to click on the row and display the value of that row. 6)

FlexiLayout: FlexiLayout is a layout manager that allows you to define custom layouts in simple java code. 7) WYSIWYG: You can edit the position and size of components by clicking and dragging them. 8) Excel-like grid: You can have a grid with columns and rows. The

items in the grid are arranged in the defined order. This is very useful for creating fixed layouts.

9) Auto complete: You can use the auto complete to enter text in a

component. 10) View:

You can view the components from the left window. This window is a "trellis" style, so you can scroll the left window to view all components. 11)

Page: You can place multiple pages inside a window, and you can create a custom layout to separate the pages. 12)

Software Architecture [?]

Software architecture is
the organized analysis of
the software development
lifecycle (SDLC) into
discrete and explicit
phases. Each phase usually
involves several steps and
creates artifacts. Each
artifact is a software
resource that is consumed

in a later phase of the SDLC. [?] The lifecycle consists of the following phases: Requirement Analysis, Requirements Engineering, Construction, Construction Management, Installation, [?] Testing, Maintenance and Operation, Destruction. It should be noted that different companies use slightly

different ways to describe the lifecycle; however, each approach is not incompatible. ☐ Software testing is the process of determining the quality of software. The test may be performed during the life cycle of the software or after the software has been released to end users. The purpose of testing is to find and correct software defects

so the software does what it is supposed to do.

Testing may also be performed as a precursor to software release, to identify what must be done to ready the software for release. [?] Software testing is the process of determining the quality of software. The test may be performed during the life cycle of the software or after the software has
