The first generation of AutoCAD lacked the pre-programmed command set of most other CAD programs, and the user interface (user interface) was a non-standardized command menu interface with separate tools that resembled a spreadsheet. The program was developed by engineers who saw the process of design as distinct from the tools available in the industry, and who wanted to streamline the design process by reducing the time spent searching for the right tool among the myriad of similar-looking tools. It was also developed by the Autodesk product management team to help company salespeople by replicating the look and feel of their other desktop programs. The result was an interface that was easy to use with a low learning curve, but which also lacked many of the more advanced features of other CAD programs. Its command set, which has only minor variations in the subsequent versions, was derived from drafting skills. Although AutoCAD lacked the more complex features of other CAD programs, its functionality was sufficient to allow designers to create drawings for most projects. Design: There are two main ways of using AutoCAD: drawing and documentation.

The drawing feature is the most commonly used application of AutoCAD. It is the way to create a drawing or a sheet, so the drawings are called sheets. Sheet The autoCAD sheet is the term for the AutoCAD document object. The sheets that make up a drawing are not static and can be changed by the user at any time. A drawing is made up of a set of sheets. Each sheet has a name, description, dimensions and layers. Sheet Settings There are different type of sheets that can be created. The standard sheets are named Sheet1 through Sheetn. The Sheetn option allows the user to create unlimited numbers of sheets. The user can select a specific sheet by assigning a name to the sheet. Once a sheet is named, the user can change its dimensions and its description. The description can be filled with a name or an image. Layer Settings The layers of a drawing can be named, dimensioned and annotated. A layer is a setting that defines the viewing transparency of a drawing. A drawing has a number of layers and can contain an unlimited number of layers. The user can name and dimension all the layers of a drawing, and can attach a title and description to each layer. The user can remove the drawing from a layer. Selection Settings The user can select any object

Spatial designations such as walls, floors, roofs, bays and window and door openings are introduced to the partitioning system. Existing partition types can also be rearranged and renamed, allowing them to be used to segment a drawing. Line colors. Line colors are now defined by the new palette Color1 to Color32, and the palette Color1 to Color8 is retained for existing line colors. MPI User-defined bridges and bridge block data can now be directly accessible from AutoCAD. Multilevel components can now be dragged and dropped between design levels, and can be directly edited in the 3D workspace. Components can be made to adhere to the dimensions of any object. Now, dimensions can be taken from any selected object. Preview. I've read a few questions on this but I'm still stuck on my current situation. I have a form in my view that I need to validate. I want to trigger an AJAX request when someone types in that specific input. I know I can use the \$.live() function to find the element that has the input and make the ajax request when it's clicked, but since the function has to wait until the input is actually submitted, the ajax request won't fire until then. I want to avoid this. Is there a way to find the specific element and make an AJAX request when someone types in that element? A: As of jQuery 1.7+, the native "onkeydown" event is supported (see the docs). \$("selector").on("keydown", function(e){ //the event was triggered by a keypress }); ^ℓ4^I am grateful to the following experts for their kind help in reviewing the manuscript and/or giving
